EUSN 2014, Barcelona

Outline of Part 2

- 1 Network objects
- 2 Packages igraph and network
- 3 Package intergraph
- 4 Vertex and edge sequences
- 5 Subgraphs and components
- 6 Visualization
- 7 Examples of descriptive SNA

Focus on **igraph** with pointers to **network**.

R

Data used in part 2

- [io](#) Directed weighted graph of commodity flows between 21 industrial sectors in US (source: Bureau of Economic Analysis)
- [ibe43](#) Primary school classroom network, "With whom would you like to play with?". Source: (Polish) Institute for Educational Research (IBE)

Outline

- 1 Network objects
- 2 Packages igraph and network
- 3 Package intergraph
- 4 Vertex and edge sequences
- 5 Subgraphs and components
- 6 Visualization
- 7 Examples of descriptive SNA

Network objects

Packages **igraph** and **network** provide dedicated types of objects (classes) for storing network data:

- Package **igraph** provides objects of class "igraph".
- Package **network** provides objects of class "network".

Apart from storing relational data (nodes and ties), objects can also store node-, tie-, and network-level variables (called attributes).

"igraph" objects can be created

- from scratch using **graph** function.
- from adjacency matrices using **graph.adjacency**.
- from edgelists using **graph.edgelist**.
- from edge and vertex data frames using **graph.data.frame**.
- from specialized file formats: Pajek, GraphML, etc. with **read.graph**.

Basic properties of networks

- Network size and number of edges: `vcount` and `ecount`.
- `graph.density`
- Extracting relational information with `get.adjacency`, `get.edgelist`
- "Simplifying" networks by removing loops (self-edges) and/or multiple edges with `simplify`.

Vertex- / edge- / graph-level attributes

Attributes can be used to store additional information on nodes (e.g. gender), ties (e.g. value, strength), or network as a whole.

- Retrieve attributes with `get.vertex.attribute`, `get.edge.attribute`, and `get.graph.attribute`.
- Set attributes with `set.vertex.attribute`, `set.edge.attribute`, and `set.graph.attribute`.

► `rsna.R`: Basic properties

Outline

- 1 Network objects
- 2 Packages igraph and network
- 3 Package intergraph
- 4 Vertex and edge sequences
- 5 Subgraphs and components
- 6 Visualization
- 7 Examples of descriptive SNA

Packages **igraph** and **network**

Package **igraph**

- Binary directed or undirected networks
- Vertex/edge/network attributes
- Multiple ties per dyad
- Loops
- Bipartite networks

Package **network** adds

- Hypergraphs
- Encoding missingness of nodes/ties

Using them together can give some headaches. . .

igraph and network clashes and how to avoid them

There are several function name conflicts between **igraph** and **network**.

- The order in which packages are loaded matters.
- How to make sure that a proper version of the function is used?

Two suggested strategies:

- 1 Always detach the package that you are not about to use.
- 2 Explicitly specify from which package the conflicting function should be used with the `::` operator.

► rsna.R: Packages igraph and network

Outline

- 1 Network objects
- 2 Packages igraph and network
- 3 Package intergraph**
- 4 Vertex and edge sequences
- 5 Subgraphs and components
- 6 Visualization
- 7 Examples of descriptive SNA

Conversions `igraph` \Leftrightarrow `network` with `intergraph`

Package `intergraph` provides two functions for converting "igraph" objects to "network" and vice versa:

- `asIgraph`
- `asNetwork`

All the attributes are copied appropriately.

► `rsna.R`: Package `intergraph`

Outline

- 1 Network objects
- 2 Packages igraph and network
- 3 Package intergraph
- 4 Vertex and edge sequences**
- 5 Subgraphs and components
- 6 Visualization
- 7 Examples of descriptive SNA

Vertex and edge sequences

Vertex and edge sequences allow for

- Vertex and edge subscripting.
- Retrieve and set attributes of vertexes/edges.
- Identify edges based on incident vertexes and vice versa.

Vertex and edge sequences are created using functions **V** and **E** respectively. For example (**E** works in a similar way):

```
V(g)[ i ]$attrname
```

- **g** is an "igraph" object
- **attrname** is an optional name of vertex attribute
- Within **[]** we can
 - Subscript vertexes just like elements of a vector.
 - Use special functions exploiting adjacency information.

Outline

- 1 Network objects
- 2 Packages igraph and network
- 3 Package intergraph
- 4 Vertex and edge sequences
- 5 Subgraphs and components**
- 6 Visualization
- 7 Examples of descriptive SNA

Subgraphs and components

Vertex and edge sequences are useful when we want to create a subgraph depending on the values of vertex or edge attributes.

- Create subgraphs using `induced.subgraph`, `delete.edges`, or `delete.vertices`.

Function `clusters` identifies weakly and strongly connected components, which can be extracted using `induced.subgraph`.

► `rsna.R: Subgraphs and components`

Outline

- 1 Network objects
- 2 Packages igraph and network
- 3 Package intergraph
- 4 Vertex and edge sequences
- 5 Subgraphs and components
- 6 Visualization**
- 7 Examples of descriptive SNA

Customizing network visualizations

- Several network layouts, see help of `layout`.
- Customizing graphical elements
 - Node size, shape, color
 - Edge color, width, curvature
 - Vertex label color, font, size

See `help("igraph.plotting")`.

- Vertex and edge attributes like `color` or `size` etc. are interpreted like corresponding arguments to `plot`.

► rsna.R: Visualization

Outline

- 1 Network objects
- 2 Packages igraph and network
- 3 Package intergraph
- 4 Vertex and edge sequences
- 5 Subgraphs and components
- 6 Visualization
- 7 Examples of descriptive SNA**

Selected SNA descriptives

- Dyad census (`dyad.census`)
- Triad census (`triad.census`)
- Network diameter: `diameter`, `get.diameter`
- Centrality indices: `betweenness`, `evcent`, `closeness`.
- Network segregation: computing mixing matrix and E-I index.
